Abstract. In this letter we present the results of a wavelet analysis of the radio light curve of the BL Lac Object PKS B0048–097 from the University of Michigan Radio Astronomy Observatory monitoring program at 8 GHz during twenty-five years, from 1979 to 2004. The results show a remarkable periodicity of 450–470 days in the early 1980s that changed to a ~ 585 day periodicity in the late 1980s to early 1990s. A less pronounced ~ 400 day periodicity is found after ~ 1995 . Very-long-baseline interferometry imaging at 15 GHz shows dramatic structural changes in the usually unresolved source between two epochs, 1995.57 and 2002.38. The pronounced northward directed jet seen in the 2002 image differs by more than 90° in direction from the source structure found in earlier epochs. These findings make PKS B0048–097 a primary target for multi-wavelength observations and intensive radio monitoring to decipher the blazar-variability phenomenon.

Key words. BL Lacertae objects: individual (PKS B0048–097) – galaxies: active – galaxies: jets

1. Introduction

Combined multi-frequency (radio to X-ray/ γ -ray) observations of active galactic nuclei (AGN) can yield important insights into the physics of relativistic outflows associated with super-massive black holes. In particular the emission of blazars (BL Lac objects and OVV quasars, see Ulrich, Maraschi & Urry 1997 for a description on the nature of blazars) is believed to be dominated over the whole electromagnetic spectrum by the most compact regions of relativistic jets. Blazars exhibiting quasi-periodic behaviour in principle allow the inter-relation between the compact radio jet and the broadband spectral energy distribution to be deciphered via quasi-simultaneous multi-frequency observations, especially if the time scales are small enough to consider variability data over multiple cycles, but such objects are rare.

Hughes, Aller, & Aller (1998) find a persistent modulation of the total flux and polarisation of the BL Lac object OJ 287. The dominating period of ~ 1.12 yr in the 1980s was later displaced by a strong ~ 1.66 yr periodicity during the 1990s. The relationship between these two variations was interpreted by Hughes, Aller, & Aller (1998) in terms of a “shock-in-jet” model while the complex periodic

optical variability of OJ 287 (period between major outbursts ~ 11.6 yr), has been interpreted, e.g., in terms of a “precessing-jet” model by Abraham (2000). Stirling et al. (2003) suggest an oscillating “nozzle” structure of the inner jet of BL Lac with a period of ~ 2 years, based on radio millimetre flux-density monitoring and VLBI observations between 1998 and 2001 (see also Mutel & Denn 2005). Villata et al. (2004) analyse the optical and radio long-term variability of BL Lac and find a gradually lengthening ~ 8 yr periodicity. The optical and radio long-term variability of the BL Lac object AO 0235+16 has been investigated by Raiteri et al. (2001) revealing a possible 5–6 year periodicity based on long-term monitoring data, in the radio regime particularly on data of the UMRAO¹ database. Ostorero, Villata & Raiteri (2004) applied the helical jet model of Villata & Raiteri (1999) to the case of AO 0235+16, interpreting the data in terms of Doppler factor variations due to changes of the viewing angle because of the helix rotation. In all these cases, attempts have been made to understand the periodic behaviour as a result of orbital motion of two black holes in a binary

system, helical jet structures, shocks, and instabilities of the disk or jet-plasma flow.

In this letter, we report on the detection of a particularly strong, and persistent quasi-periodic long-term modulation of the compact-jet emission of the BL Lac object PKS B0048–097. The comparatively short time scale of ~ 350 days to ~ 600 days and the large amplitude of the variability make PKS B0048–097 a particularly well-suited source for future multi-frequency campaigns on the broadband spectral emission of blazar sources and tests of blazar-periodicity models.

In Sect. 2, we present the observational data and their analysis. We discuss the results of a cross-wavelet analysis of twenty five years of the University of Michigan Radio Astronomy Observatory (UMRAO) monitoring of PKS B0048–097 and discuss its parsec-scale structure during two epochs observed as part of the Very Long Baseline Array (VLBA) 2 cm Survey. Finally, we summarize our results and their implications for future blazar studies, in Sect. 3.

2. Background, Observations and Analysis

PKS B0048–097 is a BL Lac object with unknown redshift. A lower limit of $z = 0.5$ is postulated by Falomo (1996) from *HST* data. The flux density of PKS B0048–097 has been measured since 1979 at 4.8 GHz, 8.0 GHz, and 14.5 GHz using the University of Michigan 26 m paraboloid. The source is observed once every three months at all three frequencies as part of the UMRAO BL Lac Observing Program (Aller et al. 1999; Aller, Aller & Hughes 2003). Its light curve is best sampled at 8.0 GHz (see Fig. 1) exhibiting pronounced maxima during several well defined time periods.

2.1. Wavelet Analysis

We used a continuous wavelet analysis, which quantifies the behaviour of a signal on different temporal scales, to investigate the available UMRAO data for periodicities. As a function of time, the signal is convolved with a localised wave-packet, that is translated along the series, for a number of ‘dilations’ of the wave-packet (Hughes et al. 1998). This technique has the great advantage of preserving temporal locality: a gap in the time series will be evident along the corresponding line in transform space, and events that are distinct in the signal will have distinct counterparts in transform space. A Morlet wavelet is particularly suited to the analysis of time series, as it is complex, so the real part of the transform exhibits an oscillatory behaviour corresponding to periodicity in the time series, while the modulus provides a measure of the power in different components of the signal.

Such an analysis has been applied to the time series for PKS B0048–097, and, as seen in Fig. 1, a distinct pattern is seen in both the real part of the source wavelet transform, and its modulus, corresponding to a quasi-periodic component containing a modest fraction of the

Fig. 1. A continuous Morlet wavelet transform of the time series data of the flux density for PKS B0048–097 taken at the UMRAO at 8.0 GHz. The panels show the flux density time series (top), the real part of the transform (middle) and the modulus (power) of the transform (bottom). The real part displays clearly the signature of a quasi-periodic component with a slowly varying ~ 1 –2 yr period. Power at this dilation extends across the entire series. The horizontal lines in the middle and bottom panel enclose the 95 % significance region of the detected periodicity determined by a cross-wavelet transform analysis (see text). The hatched areas of the transform panels show the cone of influence, where edge effects resulting from the finite length of the time series decrease the wavelet coefficient power by more than a factor e^2 .

overall power, and masked in a Fourier power spectrum, because of drifts in time scale across the data window. In the cross wavelet transform technique, described, e.g., by Kelly et al. (2003), the continuous transform of the signal is convolved with a set of template periodic signals. This analysis has been used to quantify the result (apparent on visual inspection of the top panel at Fig. 1), establishing a time scale of 385–470 days with a confidence of $> 99.9\%$ that this component does not arise by chance from random patterns associated with a lag-1 autoregressive process.

The varying time scale of the disclosed periodicity has been further investigated using a Lomb-Scargle pe-

Fig. 2. Lomb-Scargle periodogram for three different parts of the time series of UMRAO PKS B0048–097 8 GHz monitoring data. The dotted and dashed vertical lines show the 95% and 99.9% significance lines, respectively, derived from the cross wavelet transform of the full light curve.

riodogram analysis (Lomb 1976, Scargle 1982). In a L-S periodogram, the classical discrete Fourier periodogram is redefined in such a manner to as to make it invariant to a shift of the origin of time. The L-S periodogram analysis has been performed using the PERIOD software package². The L-S analysis between November 1979 and September 1985 shows maximal power at ~ 400 – 460 days and a secondary signal at ~ 580 days (see Fig. 2). Between October 1985 and February 1995, only one narrow peak at ~ 585 days is present. After October 1995, the highest power is found at a time scale of ~ 405 days, that is considerably less pronounced than the periodicities at the earlier time ranges. The significance of the individual peaks in Fig. 2 is difficult to quantify because of the not *a-priori* known frequency dependence of the underlying noise process³. We base our detection on the highly-significant signal in the global power spectrum. Figure 2 illustrates that over the full ~ 25 years of UMRAO 8 GHz radio light curve monitoring of PKS B0048–097 the maximal power found by the L-S analysis is located within the significance ranges found by the cross-wavelet analysis, but that its time scale and power vary with time.

² The PERIOD software package is provided by the Starlink Project which was run by CCLRC on behalf of PPARC. See <http://star-www.rl.ac.uk>

³ Only the assumption of a white noise process would allow a simple significance threshold parallel to the frequency axis to be placed. Admitting a red noise process would require us to consider a range of possible power laws for the process, which would lead to a range of significance areas (not parallel to the frequency axis). Note, that the formal L-S false-alarm-probability lies below 1% (with 95% confidence) for all major peaks in Fig. 2

2.2. Structural Variability

On parsec scales, Shen et al. (1997) and Gabuzda, Pushkarev & Cawthorne (1999) both report a core-jet morphology of PKS B0048–097, however the reported jets differ by ~ 40 degrees in position angle (P.A.). While Shen et al. (1997) report a P.A. of $\sim -160^\circ$ (south-westward) in epoch 1992.9 from 5 GHz VLBI observations, Gabuzda et al. (1999) find a jet at P.A. $\sim +160^\circ$ (south-eastward) in epoch 1992.2 also from 5 GHz data. In both cases the (u, v) -coverage was not optimum. In the VLBA 2 cm Survey observations before 2002, PKS B0048–097 showed no clear resolved structure. Figure 3 shows the milliarcsecond structure of PKS B0048–097 in epochs 1995.57 and 2002.38 (compare Table 1). In 1995.57, a weak westward directed jet is found, partially resolved only by the longest east-west baselines. The (u, v) -data obtained in 2002.38 show clear evidence for a resolved north-south structure along P.A. $\sim -30^\circ$ with the jet pointing in a direction more than 90° different from what was reported by Shen et al. 1997 and Gabuzda et al. (1999). Considering these discrepancies between different works, PKS B0048–097 might represent a case of extreme jet-ejection-angle variation. This would be of particular interest in conjunction with a putative periodicity of the radio light curve as revealed from the UMRAO data above. In the scenario of a precessing jet, PKS B0048–097 might represent a highly attractive target to study the broadband jet emission of a BL Lac object at different angles to the line of sight.

On the basis of the available data, it is not possible to derive the time scales of the structural variability. VLBA 2 cm Survey observations of PKS B0048–097 have been conducted during two additional epochs between 1995 and 2002 but the data quality in both cases does not allow us to compare the milliarcsecond structure directly to the two images presented here, due to shorter integration times and sub-optimal (u, v) -coverage. After 2002, the source has been observed several times as part of the VLBA 2 cm Survey continuation project, MOJAVE. An analysis of these observations, which provide full polarimetric information, is currently being performed. A first MOJAVE image of PKS B0048–097 in 2003 showing a northward-directed jet similar to the 2002 source structure can be found in Lister & Homan (2005).

3. Summary and Implications

The BL Lac object PKS B0048–097 exhibits strong structural variability on sub-milliarcsecond scales and pronounced radio, optical (see, e.g., Pica et al. 1988) and X-ray flux variability. We have demonstrated that the radio light curve of PKS B0048–097 has a strong modulation with a period of ~ 350 days to ~ 600 days at 8 GHz. Additional insight may be gained from future polarimetric studies which have not been considered in this letter. From all wavelet transforms of sources monitored as part of the UMRAO program, only for OJ 287 a comparably strong persistent signal has been found. The strength of

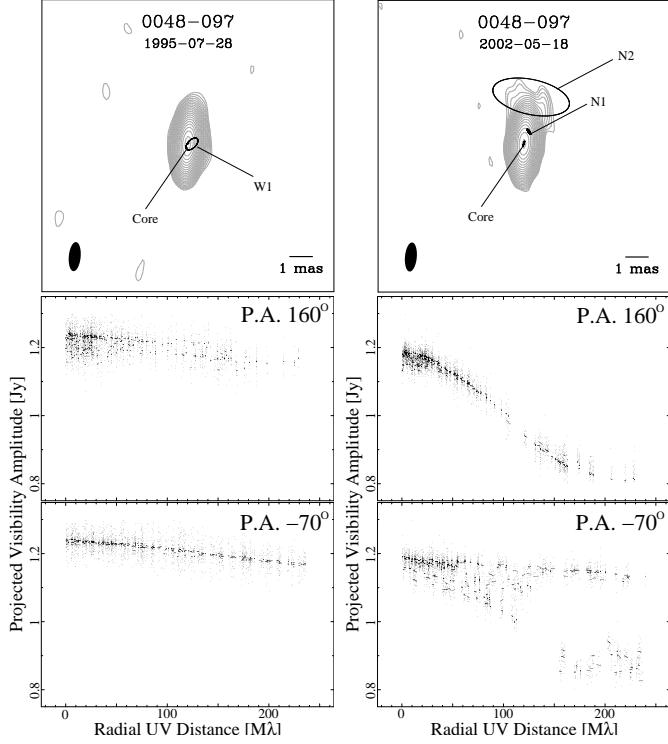

Fig. 3. VLBI results of PKS B0048–097 at 15 GHz. Top Panels: Naturally weighted images of PKS B0048–097 in 1995.58 (left) and in 2002.38 (right) at $\lambda 2$ cm obtained from VLBA 2 cm Survey observations. Image parameters are given in Table 1. A jet towards the north is visible in the 2002 image while a slight extension to the west is seen in the earlier 1995 image. Best fitting Gaussian-model-component approximations to the (u, v) -data are indicated as ellipses. Middle and bottom panels: The projected visibility along P.A. 160° and -70° for both epochs. Clear deviations from a flat point-source visibility indicate an elongation of the source along different position angles.

Table 1. VLBI Results

Epoch	Image parameters ^a			Model fit parameters ^b

the modulation and the comparatively short time scale makes PKS B0048–097 a prime object for coordinated broadband observing campaigns. In particular, the correlation of the varying VLBI-jet ejection angle of the source with radio (and higher energy) light-curve evolution pro-

vides a tool to test precessing-jet models against alternative models (e.g., intrinsic instabilities of the flow) of periodic light-curve modulation in blazars. Unlike most other sources, the short 350 day to 600 day time scale of PKS B0048–097 allows these alternatives to be tested observationally in a relatively short time.

Acknowledgements. We thank the referee, Claudia M. Raiteri, for her valuable suggestions on improving the paper.
